## WEEK 6: Circular Motion

### Meaning of Circular Motion

Circular motion is the motion of a body around a circle. The simplest form of circular motion is the uniform circular motion, where the speed is constant but the direction is changing.

Consider a body moving in a circular path center O with a constant speed.

1. The direction at different points are not the same i.e. the direction at A is different from the direction at B. This leads to a change in velocity.
2. This difference in velocity produces an acceleration directed towards the center of the circle. This acceleration is called ***centripetal acceleration***.

3. Since there is an acceleration, there is a force directed towards the center of the circle called ***centripetal force***.
4. In addition to the centripetal force, there is an equal but opposite force which acts outwards from the center of the circle. This force is called the ***centrifugal force***. The centripetal and the centrifugal forces enable the object to move in the orbit.

## Definition of Terms Used in Circular Motion

### 1. Angular velocity ( $\omega$ ):

The ratio of the angle turned through to the elapsed time.

$\omega$  = Angular velocity

$\omega = \frac{\text{angular displacement}}{\text{time}} = \frac{\theta}{t}$

The S.I unit is rad/sec

### 2. Tangential velocity (**V**):

This is the linear velocity whose direction is along the tangent to the circumference of the circle.

$V = \frac{\text{displacement}(s)}{\text{time}(t)} = \frac{s}{t} = r\omega$

But  $\omega = \frac{\theta}{t}$

Then  $V=r\omega$

The unit is m/s

### 3. Centripetal acceleration (a):

This can be defined as the acceleration of a body in uniform circular motion whose direction is towards the centre of the circle. It is given as:

$$a = \frac{V^2}{r}$$

The unit is  $\text{m/s}^2$

But  $V=r\omega$

Then  $a=r\omega^2$

### 4. Centripetal force (F):

It is defined as that inward force that is always directed towards the centre of the circle required to keep an object moving with a constant speed in a circular path.

Centripetal force = mass  $\times$  centripetal acceleration

$$F = \frac{mv^2}{r} \text{ or } F = m\omega^2 r$$

$$F = r\omega^2 = \omega V r = ma$$

The unit is Newton

### 5. Centrifugal force:

This force is equal in magnitude to the centripetal force but opposite in direction. (it is always directed away from the centre of the circle)

$$F = -\frac{mv^2}{r} \text{ or } F = -r\omega^2$$

### 6. Period (T):

This is the time taken for a body to complete one revolution round the circle.

Displacement = 2

Time = T

Velocity =  $v$

$$v = \frac{\text{displacement}}{\text{time}} = \frac{2\pi r}{T} = 2\pi r v$$

### 7. Frequency (f):

It is the number of revolutions in one second.

$$f = \frac{1}{T} = \frac{v}{2\pi r}$$

The unit is Hertz or per seconds. (i.e Hz or  $s^{-1}$ )

## Calculations on Circular Motion

### Question 1:

A stone of mass 2kg is attached to the end of an inelastic string and whirled round two times in a horizontal circular path of radius 3m in 3 sec, find:

- (i) Angular velocity
- (ii) Linear velocity
- (iii) Centripetal acceleration
- (iv) Centripetal force
- (v) Centrifugal force

### Solution

(i)  $\omega = \frac{\text{angular displacement}}{\text{time}} = \frac{\theta}{t}$

Where  $\theta$  is the angular displacement and  $\omega$  is the **angular velocity**

$$\theta = 360^\circ \times 2 = 720^\circ \text{ (ie two times)}$$

$$\pi = 180^\circ \Rightarrow \theta = 4\pi \text{ rad} \quad \omega = \frac{4\pi}{3} = 1.33\pi \text{ rad/sec}$$

(ii)  $v = r\omega = 3 \times 1.33\pi = 3.99\pi \text{ m/s}$

(iii)  $a = \frac{v^2}{r} = \frac{(3.99\pi)^2}{3} = 5.31\pi^2 \text{ m/s}^2$

(iv)  $F=ma=2\times 5.31\pi^2=10.62\pi^2\text{N}$

(v)  $F=-mv^2r=-10.62\pi^2\text{N}$
